

Class model: relationships (multiplicity)

How to read it (always from one end to the other):

- One Customer makes 0..* Rentals; each Rental is made by exactly 1 Customer.
- One Vehicle is used in 0..* Rentals; each Rental is for exactly 1 Vehicle.

Notation	Meaning	AutoRent example
1	Exactly one (mandatory)	Each Rental has exactly 1 Customer
0..1	Zero or one (optional)	A Rental has 0..1 Inspection recorded so far
1..*	One or many (at least one)	A Branch has 1..* Sales Persons
0..*	Zero or many	A Customer makes 0..* Rentals

Multiplicity states the business rules of the data: how many of one thing can be linked to another.

Personas

A persona is a fictional but realistic profile of a typical user within a user role, used to bring requirements to life and test whether the solution serves real people.

Maria, 28

Tourist | User role: Customer

Goals

- Book a car for a weekend trip, quickly, on her phone, the night before
- Collect the car with no paperwork and no queue

Behaviours

- Books everything on her phone, never phones a business
- Abandons any website that feels slow or asks too much

Frustrations

- Being made to call the branch to check availability
- Forms that demand information she does not have to hand

Quote

"If I cannot book it on my phone in five minutes, I will rent from someone else."

Why use personas?

- Split baggy user roles: "Customer" hides very different people with different needs
- Test requirements: "would Maria use this?" exposes gaps and wrong assumptions
- Anchor customer journey maps: the journey is walked through the persona's eyes
- Keep design honest: teams build for Maria, not for themselves

Same role, different persona: Dev, 45, books twenty vans a month on a business account. One role, two very different requirement sets.

A persona is not a real person and not an average: it is a believable, specific individual the whole team can design and test against.
